

## Kresz Egyeni Gyakorlo Program 2.81

The screenshot shows the 'Kresz 2.81' registration window. It features a blue title bar with standard window controls. The main area is a grey panel with the following elements:

- Two red boxes at the top containing 'Site kód: 0B893C6F' and 'MID kód: DACC-4B43-B4AB-1024'.
- Two input fields for 'Napok száma: N/A' and 'Használat száma: N/A'.
- A radio button for 'Enter application'.
- A radio button for 'Aktiválási kód:' with an adjacent 'Aktiválási kód' input field.
- Radio buttons for 'Remove licence' and 'Transfer licence', with an 'Új Site kód:' input field.
- A status indicator: 'A regisztráció állapota: NEM REGISZTRÁLT'.
- Buttons for 'Kilépés' and 'Regisztráció >'. The 'Regisztráció >' button is highlighted with a black border.
- A footer box containing 'Springer Media Magyarország Kft.'

-ben már nem képzelt már. A Cseh Köztársaság a címlázásra megy a kerítés, de úgy gondolja, a napi szintet megvalósítani még túl korán. Q: Retrieve SQLite Row as JavaScript Object I have read almost all of the questions here related to this topic, but couldn't find one that directly answered my question: How do I retrieve an SQLite data row from a Table with pure javascript? I want to use the object to fill a HTML form. A: With the answers you got so far I will go ahead and update this answer. The solution proposed by @astorfi is outdated. You can just use the following: `table1.getRow(rowIndex).item(columnIndex)` You can access individual cell values as follows: `table1.getRow(rowIndex).item(columnIndex).getCell(cellIndex).getText()`; And if you wanted to retrieve your data as a JSON string you could use: `table1.getRow(rowIndex).item(columnIndex).getText()`; If you want to use this in your code you can change the `getText()` method to: `table1.getRow(rowIndex).item(columnIndex).toString()`; and convert the JSON string to a JavaScript Object by using `JSON.parse()`. Happy coding. I think the most updated answer for now is to use the following: or `var data = table1.getRow(rowIndex).item(columnIndex).toString(); var data = table1.getRow(rowIndex).item(columnIndex).toString().replace(/ /g, "");` You can do a quick conversion of it to a JSON if you need to but I would suggest using the `toString()` method at the end unless you are going to manipulate it to another form later. The following code works with `sqlite3` (the `sqlite3 82157476af`
